HARMONIZATION OF ANALYSIS AND REPORTING OF
19-NORSTEROIDS RELATED TO NANDROLONE

1.0 Introduction

This document has been established to harmonize the analysis and reporting of 19-norsteroids related to nandrolone by Laboratories.

The detection of the use of nandrolone and other 19-norsteroids is based primarily upon the identification of the main urinary metabolite, 19-norandrosterone (19-NA) in a concentration (derived from hydrolysis with β-glucuronidase) greater than the Decision Limit (DL), as established in the DL Technical Document. More than one metabolite [e.g., 19-noretiocholanolone (19-NE)] of administered norsteroids may be detected and reported but the identification and quantification and the demonstration, when required, that the 19-NA metabolite does not come from endogenous origin is sufficient to report an Adverse Analytical Finding (AAF).

Under specific circumstances, as described below, additional testing and reporting may be required.

2.0 Analysis

2.1 Identification and Quantification

In addition to meeting the identification criteria described in the IDCR Technical Document, the Laboratory shall demonstrate that the concentration of 19-NA is above the DL as set out in the DL Technical Document and, when necessary, that the 19-NA detected is not of endogenous origin (through GC/C/IRMS analysis).

The quantification method used to calculate the concentration of 19-NA shall include the following characteristics:

- A deuterated internal standard (e.g., d4-19-NA-glucuronide);
- A calibration curve at an appropriate range bracketing the estimated concentration of the analyte in the Sample (when the concentration is at or below 15 ng/mL) or a single calibration point at 15 ng/mL (when the concentration is above 15 ng/mL).
- The use of appropriate negative and positive quality control samples.

The GC/C/IRMS method shall include the following characteristics:

- Each batch of Samples analyzed by GC/C/IRMS shall include a negative control urine (δ13C values of 19-NA and endogenous reference compound – ERC – in a natural range) and a positive control urine (difference in δ13C values (Δδ) between ERC and 19-NA greater than 3‰). These controls shall be subjected to the same sample preparation procedure as the Sample test...
Aliquot. The analysis shall include the confirmation of the 19-NA peak identity (for example by GC/MS analysis performed under comparable chromatographic conditions. The purpose is to produce a chromatogram with similar peak profiles so that the spectra can be used to identify the peak(s) of interest. Minor differences in RT between the two techniques are expected).

2.2 Additional mandatory tests

19-NA is excreted at low concentrations as a minor metabolite of norethisterone, a progestogen agent of permitted use, and during pregnancy. In addition, 19-NA can be rarely produced in urine samples, at similar levels, by in-situ 19-demethylation of androsterone (A).

When the measured concentration of 19-NA exceeds the DL in the urine Sample of a female Athlete, the Laboratory shall perform methods to test for pregnancy (e.g. based on the quantification of urinary human Chorionic Gonadotrophin (hCG)) and for the use of norethisterone-based contraceptives (e.g. detection of tetrahydronorethisterone).

GC/C/IRMS analysis shall be performed in the following cases1:

- For any urine Sample when the 19-NA concentrations measured are between the DL and 10 ng/mL, except in cases of pregnancy or use of norethisterone.
- In cases of pregnancy, when 19-NA concentrations measured in a urine Sample are above 15 ng/mL2.

Laboratories that do not have the analytical capacity to perform GC/C/IRMS analysis for 19-NA, shall have the Sample analyzed by another Laboratory that has such analytical capacity.

---

1 To reject the hypothesis of endogenous 19-NA formation the following criteria, based on the application of GC/C/IRMS analysis, shall be met simultaneously:

i- The $\delta^{13}C$ value of 19-NA is outside the range of values normally measured in humans (i.e. is less than $-27^\circ/oo$), and

ii- The $\Delta\delta$ value between the endogenous reference compound (ERC) (e.g. A or pregnanediol [PD]) and 19-NA, i.e. $\Delta\delta = \delta_{ERC} - \delta_{19-NA}$, is greater than $3^\circ/oo$ and

iii- The standard combined uncertainty ($u_c$) associated with the determination of $\delta^{13}C$ values, as estimated by the Laboratory during the GC/C/IRMS method validation, is not greater than $1.0^\circ/oo$ ($u_c_{Max}$).

2 In cases of pregnancy, when the concentration of 19-NA measured in a urine Sample is between the DL and 15 ng/mL, the IRMS analysis may also be performed to ascertain the endogenous origin of 19-NA.
2.3 “B” Sample Confirmation Procedure

- “B” Sample Confirmation Procedures for Samples from males and non-pregnant females require only the identification and quantification (for Samples with 19-NA concentrations at or below 15 ng/mL) of the 19-NA reported.
- For pregnant females with urinary values of 19-NA greater than 15 ng/mL\(^2\) the “B” Sample Confirmation Procedure requires the GC/C/IRMS analysis, including the confirmation of the 19-NA peak identity.

3.0 Interpretation

3.1 Adjusted Threshold

Only in the case of urine Samples measured with a specific gravity (SG) above 1.020 (in the Laboratory), an adjustment to the Threshold (T) shall be made to take into account the SG of the Sample using the following formula:

\[
T_{\text{adjusted}} = \frac{(SG_{\text{Sample}} - 1)}{(1.020 - 1)} \times T
\]

3.2 Decision Limit for 19-NA

The DL, established for 19-NA, is published in the DL Technical Document. In cases where the SG is greater than 1.020, the DL shall be determined for the individual 19-NA test result using the SG-adjusted T in accordance with the DL Technical Document. Consequently, the adjusted DL shall be used to determine whether an AAF is reported for the Sample and included on the Laboratory test report.
4.0 Reporting

The Laboratory shall report the finding of 19-NA in a urine Sample from a male or a female Athlete at a concentration above the DL (see sections 3.1 and 3.2 above) as defined below:

A. Samples from pregnant female Athletes:

- **Samples** for which 19-NA concentrations are determined to be greater than 15 ng/mL and the mandatory GC/C/IRMS analysis (see section 2.2 above) is not consistent with the endogenous origin of the 19-NA detected shall be reported as an AAF for 19-NA. The results of the GC/C/IRMS analysis shall be included in the test report.

- **Samples** for which 19-NA concentrations are determined to be greater than 15 ng/mL and the mandatory GC/C/IRMS analysis (see section 2.2 above) is consistent with an endogenous origin of the 19-NA detected, shall be reported as “No Prohibited Substance or Method on the test menu was detected”.

- **Samples** for which 19-NA concentrations are determined to be at or below 15 ng/mL shall be reported as “No Prohibited Substance or Method on the test menu was detected”. However, if GC/C/IRMS analysis (see section 2.2 above) is performed on such a Sample and its results are not consistent with the endogenous origin of the 19-NA detected the Sample shall be reported as an AAF for 19-NA. The results of the GC/C/IRMS analysis shall be included in the test report.

In either case, no reference to the pregnancy status of the Athlete shall be made.

---

3 Reported 19-NA concentrations shall be expressed as follows:

- When the 19-NA concentration is greater than 15 ng/mL, no quantification is required during the Confirmation Procedure. The application of a single calibration point at 15 ng/mL is sufficient. The estimated concentration shall be expressed as “>15 ng/mL” without the need for reporting the estimated value;

- When the 19-NA concentration is determined to be between the DL and 15 ng/mL, quantification is required for the Confirmation Procedure. The confirmed value shall be expressed as the mean concentration from triplicate determinations reported to not more than two significant figures (a result between 2 and 10 would be reported, for example, as “5.1 ng/mL”. A result between 10 and 15 would be reported as “13 ng/mL”).

In every case, in accordance with the Technical Document on DL, the Laboratory shall report the DL for 19-NA and the combined standard uncertainty \((u_c)\) estimated by the Laboratory at the Threshold limit.

---

4 The test report for the GC/C/IRMS analysis shall include a comment indicating that the GC-C-IRMS finding is consistent with an exogenous origin of 19-NA, the \(\delta^{13}C\) values for 19-NA and ERC as well as the associated \(u_c\) expressed in units.
B. Samples from female Athletes using norethisterone:

- Samples for which 19-NA concentrations are determined to be greater than 10 ng/mL shall be reported as an Atypical Finding (ATF) for 19-NA\(^3\). A comment shall be added to the test report describing the 19-NA finding together with the finding that demonstrates the use of norethisterone (e.g. “19-norandrosterone (19-NA) was found in the Sample at a concentration ‘X’\(^3\). Tetrahydronorethisterone, a metabolite of norethisterone, was also found in the Sample”).

- Samples for which 19-NA concentrations are determined to be equal to or less than 10 ng/mL shall be reported as “No Prohibited Substance or Method on the test menu was detected” with no further comment (no reference to the use of norethisterone shall be made).

C. Samples from male or females Athletes (not covered under A or B):

- Samples for which 19-NA concentrations are determined to be greater than 10 ng/mL shall be reported as an AAF for 19-NA\(^3\). For female Athletes, a comment shall be added explaining that pregnancy and norethisterone tests were performed and the result is not consistent with any of those conditions (e.g. “the 19-NA finding is not consistent with pregnancy or the use of norethisterone”).

- Samples for which 19-NA concentrations are determined to be between the DL and 10 ng/mL and the mandatory GC/C/IRMS analysis (see section 2.2 above) is not consistent with an endogenous origin of the 19-NA detected shall be reported as an AAF for 19-NA\(^3\) and the results of the GC/C/IRMS analysis shall be included in the test report\(^4\).

- Samples for which 19-NA concentrations are determined to be between the DL and 10 ng/mL and the mandatory GC/C/IRMS analysis (see section 2.2 above) is consistent with an endogenous origin of the 19-NA detected shall be reported as “No Prohibited Substance or Method on the test menu was detected”. A comment shall be added describing the 19-NA finding and explaining that the GC/C/IRMS analysis is consistent with endogenous production of 19-NA (e.g. “19-norandrosterone (19-NA) was found in the sample at a concentration ‘X’\(^3\) and the results of GC/C/IRMS analysis indicate that the 19-NA finding may be consistent with endogenous production”).

Annex A – Flowchart for 19-NA findings

**Initial Testing Procedure**

19NA > SG-adjusted DL?

**YES**

**Female Athlete**

Test for Pregnancy / Norethisterone

**Cases**

- **Case A**: Sample from pregnant female Athlete
- **Case B**: Sample from female Athlete using Norethisterone
- **Case C**: Sample from male or female Athlete (not A or B)

**Confirmation Procedure**

1. Identification
2. Quantitation

If 19NA < 15 ng/mL

- IRMS: "No Prohibited Substance detected"
- ATF: "No Prohibited Substance detected"

Endogenous

Non-endogenous

- Confirmation Procedure
  1. Identification
  2. Single Point Calibration

If 19NA > 15 ng/mL

- Confirmation Procedure
  1. Identification
